## Introduction

Optically active alcohols and amines are useful intermediates of pharmaceuticals or pesticides. Chiral ruthenium complexes with chiral diamine ligands, which were discovered by NOYORI Molecular Catalysis Project of Exploratory Research for Advanced Technology (ERATO) by Japan Science and Technology Corporation (JST), are extremely effective catalysts for the asymmetric transfer hydrogenation of ketones<sup>1)-11)</sup> and imines<sup>9), 12), 13)</sup> leading to optically active alcohols and amines with high optical purities in high yields.

As organic compounds such as 2-propanol and formic acid are used as hydrogen donors in this asymmetric reaction, this reaction can be easily implemented using laboratory equipments such as flasks and is therefore highly versatile.

KANTO CHEMICAL CO.,INC. launches of pre-formed chiral ruthenium complexes, which are easily handled and can be used for this asymmetric transfer hydrogenation.

### Asymmetric Transfer Hydrogenation Catalysts

#### Amide complexes

## 1. Asymmetric transfer hydrogenation of ketones<sup>1)-10)</sup> (Synthesis of optically active secondary alcohols)

### 《Selection of hydrogen donors》

Organic compounds such as 2-propanol and formic acid can be used as the hydrogen donors for this reaction. As the reaction in 2-propanol is reversible, the reaction is proceeded after adjusting the substrate concentration and S/C (the substrate/catalyst molar ratio). Conversely,

the reaction which uses formic acid as a hydrogen donor is not reversible, and therefore even if the reaction is implemented with a high substrate concentration or high S/C, a high yield of optically active alcohols with high optical purities can be obtained.

●Reaction with the 2-propanol as a hydrogen donor<sup>1), 4)-6), 8)</sup>

## 《Selection of substrates》

In addition to the simple ketones referred to above, the reaction can also proceed efficiently and without loss of the functional group in the case of ketones that have a functional group such as a carbon-carbon multiple bond or a heteroatom, producing optically active alcohols with high optical purities. For example, acetylenic alcohol with 97% ee can be obtained in a high yield by a reaction of acetylene-ketone. The reaction of ketones that have a furan ring or thiophene ring also proceed properly, resulting in alcohols with high optical purities. Moreover ketone having a pyridyl group also react well, resulting in optically active pyridyl alcohol with 95% ee. This reaction can also be applied to the reaction of ketones that have a multiple number of functional groups

such as a pyridyl group, carbon-carbon multiple bond or an ester group, allowing the successful synthesis of the key intermediate of a carbonic anhydrase inhibitor, MK-0417. Furthermore, the reaction of unsymmetrically substituted 1, 2- diketones leads to optically active  $\alpha$ -hydroxyketones or optically active 1, 2- diols separately depending on the reaction conditions. Further, the reaction of acetophenone derivatives with a cyano group, azido group or nitro group in the second position also proceeds efficiently, producing optically active alcohols. These compounds can be easily reduced by usual reducing agents, leading to optically active amino alcohols, which are useful synthetic intermediates for pharmaceutical products.

## 2. Asymmetric transfer hydrogenation of benzyls<sup>11)</sup> (Synthesis of optically active hydrobenzoin)s

Benzyls can be rapidly reduced at room temperature with a chiral ruthenium catalyst in a mixture of formic acid/triethylamine, producing optically active

hydrobenzoin)s with high optical purities almost quantitatively.

## 3. Kinetic resolution of secondary alcohols<sup>4), 12)</sup>

As asymmetric transfer hydrogenation in 2-propanol is a reversible reaction, it has previously been difficult to implement the high enantioselectivities in the reduction of high-reduction-potential ketones with an electron donating group on the aromatic ring. However, through

the kinetic resolution of racemic alcohols using a chiral ruthenium catalyst, optically active alcohols with high optical purities are now obtainable. This method can also be applied to the synthesis of natural products such as (-)-chokol G<sup>14)</sup> and (-)-pentenomycin<sup>15)</sup>.

#### 4. Asymmetric transfer hydrogenation of imines <sup>4), 15)</sup>

Up until now, it has been difficult to achieve the efficient synthesis of optically active amines through the catalytic asymmetric hydrogenation of imines. However, the

reduction of imines using this catalyst is efficient, and optically active amines with a high optical purities can be obtained in high yields.

## Standard operating procedures for the asymmetric transfer hydrogenation of ketones

Example procedures are shown below for the 1) production of optically active alcohols by the reduction of the ketonic substrates<sup>2)</sup> and 2) production of optically active hydrobenzoin from benzyl<sup>11)</sup>, both using a chiral ruthenium catalyst in a mixture of formic acid and triethylamine.

### 1) Synthesis of optically active alcohols

Under an inert gas atmosphere, add the ketonic substrate (5.0 mmol) and RuCl [(S,S)-Tsdpen] (mesitylene) (15.5mg, 0.025 mmol) into a Shrenk flask.

Mix for 48-hours at 28°C. <sup>note 3</sup>

Dilute the reaction mixture with water, and extract with ethyl acetate or similar solvents. Wash the organic layer with a sodium hydrogen carbonate solution and then with a saturated sodium chloride solution.

The optically active alcohols can be obtained through the prescribed refining operations. <sup>note 4</sup>

### 2) Synthesis of optically active hydrobenzoin

In an inert gas atmosphere, mix triethylamine (19.0 ml, 136 mmol) and formic acid (8.7 ml, 230 mmol) in a Shrenk flask while keeping the mixture cool. <sup>note 1</sup>

Mix for 24-hours at 40°C. <sup>note 3</sup>

Add water to the reaction mixture, and filter out the deposited crystals. (*R,R*)- Hydrobenzoin can be obtained from the recrystallization with ethanol. <sup>note 4</sup>

Note 1: The original research paper uses an azeotropic mixture but a mixture of formic acid and triethylamine in the optimum ratio can also be used without distillation. We recommends investigating the optimum mixture ratio of formic acid and triethylamine for the substrate, since the optimum ratio varies depending on the substrate.

Note 2: Do not induce the reaction in a closed system, since carbon dioxide will be released. For example, as shown in the photograph on the previous page, insert an inert gas line or attach a highly airtight gas balloon.

Note 3: Even if the reaction temperature is raised, the lowering of the optical yield is minimal. Therefore please optimize the reaction temperature and time according to the reactivity of the substrate.

Note 4: The residual catalyst can be removed by filtering the organic layer through a short column of silica gel.

Note 5: An optically active hydrobenzoin can also be obtained from the racemic benzoin as a high yield. See the references for details.
